Part I

Easy

Chapter 1

1. Two Sum

1.1 Description

Given an array of integers `nums` and an integer `target`, return indices of the two numbers such that they add up to `target`. You may assume that each input would have exactly one solution, and you may not use the same element twice. You can return the answer in any order.

1.2 Results

Runtime: 7 ms, faster than 97.35% of C++ online submissions for Two Sum.

Memory Usage: 11 MB, less than 29.34% of C++ online submissions for Two Sum.

1.3 Attempt 1

It's finals week so I wanted to do a easier one. Just use an unordered map for constant lookup.

```
class Solution {
public:
    vector<int> twoSum(vector<int>& nums, int target) {
        unordered_map<int, int> map;
        map.reserve(nums.size());
        map[nums[0]] = 0;
        for (int i = 1; i < nums.size(); i++) {
            if (map.find(target - nums[i]) != map.end()) {
                return {map[target - nums[i]], i};
            }
            map[nums[i]] = i;
        }
        return {};
    }
};
```

Part II

Medium

Chapter 2

2. Add Two numbers

2.1 Description

You are given two non-empty linked lists representing two non-negative integers. The digits are stored in reverse order, and each of their nodes contains a single digit. Add the two numbers and return the sum as a linked list. You may assume the two numbers do not contain any leading zero, except the number 0 itself.

2.2 Results

Runtime: 47 ms, faster than 55.66% of C++ online submissions for Add Two Numbers.

Memory Usage: 71.4 MB, less than 50.94% of C++ online submissions for Add Two Numbers.

2.3 Attempt 1 - 2022-04-23

Worked great until I realized that the numbers can be up to $9 * 10^{100}$. Turn each list into ints, sums them, and uses a recursive function to convert it back into a reversed linked list.

```
/**
 * Definition for singly-linked list.
 * struct ListNode {
 *     int val;
 *     ListNode *next;
 *     ListNode() : val(0), next(nullptr) {}
 *     ListNode(int x) : val(x), next(nullptr) {}
 *     ListNode(int x, ListNode *next) : val(x), next(next) {}
 * };
 */
class Solution {
public:
    ListNode *addTwoNumbers(ListNode* l1, ListNode* l2) {
        int place = 1;
        int s1 = 0, s2 = 0;
        while(l1) {
            s1 += l1->val * place;
            place *= 10;
            l1 = l1->next;
        }
        place = 1;
        while(l2) {
            s2 += l2->val * place;
            place *= 10;
            l2 = l2->next;
        }
        int sum = s1 + s2;
        return createNodes(sum, nullptr);
    }
    ListNode *createNodes(int x, ListNode *curr) {
        if (x >= 10)
            curr = createNodes(x / 10, curr);
        return new ListNode(x % 10, curr);
    }
};
```

2.4 Attempt 2 - 2022-04-23

The correct way to do it. Sums them just like an adder in a cpu would. Sums each digit and has a carry digit to keep track of overflows.

```
/**
 * Definition for singly-linked list.
 * struct ListNode {
 *     int val;
 *     ListNode *next;
 *     ListNode() : val(0), next(nullptr) {}
 *     ListNode(int x) : val(x), next(nullptr) {}
 *     ListNode(int x, ListNode *next) : val(x), next(next) {}
 * };
 */

class Solution {
public:
    ListNode *addTwoNumbers(ListNode* l1, ListNode* l2) {
        int sum = l1->val + l2->val;
        int carry = (sum > 9) ? 1 : 0;
        auto output = new ListNode();
        auto curr = output;
        l1 = l1->next;
        l2 = l2->next;
        if (carry == 1) {
            curr->val = sum % 10;
        } else {
            curr->val = sum;
        }
        while (l1 && l2) {
            sum = l1->val + l2->val + carry;
            carry = (sum > 9) ? 1 : 0;
            curr->next = new ListNode();
            curr = curr->next;
            if (carry == 1) {
                curr->val = sum % 10;
            } else {
                curr->val = sum;
            }
            l1 = l1->next;
            l2 = l2->next;
        }
        while (l1) {
            sum = l1->val + carry;
            carry = (sum > 9) ? 1 : 0;
            curr->next = new ListNode((carry) ? sum % 10 : sum);
            curr = curr->next;
            l1 = l1->next;
        }
        while (l2) {
            sum = l2->val + carry;
            carry = (sum > 9) ? 1 : 0;
            curr->next = new ListNode((carry) ? sum % 10 : sum);
            curr = curr->next;
            l2 = l2->next;
        }
        if (carry) {
            curr->next = new ListNode(carry);
        }
        return output;
    }
};
```

Chapter 3

1584. Min Cost to Connect All Points

3.1 Description

You are given an array `points` representing integer coordinates of some points on a 2D-plane, where `points[i] = [xi, yi]`. The cost of connecting two points `[xi, yi]` and `[xj, yj]` is the manhattan distance between them: $|xi - xj| + |yi - yj|$, where $|val|$ denotes the absolute value of `val`. Return the minimum cost to make all points connected. All points are connected if there is exactly one simple path between any two points.

3.2 Results

Runtime: 636 ms, faster than 50.33% of C++ online submissions for Min Cost to Connect All Points.

Memory Usage: 150.9 MB, less than 19.58% of C++ online submissions for Min Cost to Connect All Points.

3.3 Attempt 1

Interesting problem, not sure exactly where I went wrong. Maybe I need to use the given vector more to conserve memory.

```

class Solution {
public:
    int minCostConnectPoints(vector<vector<int>>& points) {
        int out = 0;
        bool connect[points.size()];
        memset(connect, 0, points.size());
        connect[0] = true;
        std::vector<int> dis(points.size(), INT_MAX);
        int curr = 0;
        for (int i = 1; i < points.size(); i++) {
            int min = 0;
            for (int j = 1; j < points.size(); j++) {
                if (!connect[j]) {
                    int tmp = man(points[curr], points[j]);
                    if (tmp < dis[j]) dis[j] = tmp;
                    if (dis[j] < dis[min]) min = j;
                }
            }
            connect[min] = true;
            curr = min;
            out += dis[min];
        }
        return out;
    }
    int man(vector<int> A, vector<int> B) {
        return abs(A[0] - B[0]) + abs(A[1] - B[1]);
    }
};

```

Part III

Hard

Chapter 4

4. Median of Two Sorted Arrays

4.1 Description

Given two sorted arrays `nums1` and `nums2` of size `m` and `n` respectively, return the median of the two sorted arrays. The overall run time complexity should be $O(\log(m+n))$.

4.2 Results

Runtime: 44 ms, faster than 69.41% of C++ online submissions for Median of Two Sorted Arrays.

Memory Usage: 89.7 MB, less than 42.98% of C++ online submissions for Median of Two Sorted Arrays.

4.3 Attempt 1 - 2022-04-24

Just use the given cpp merge functions. This can be further optimized.

```
class Solution {
public:
    double findMedianSortedArrays(vector<int>& nums1, vector<int>& nums2) {
        auto total = nums1.size() + nums2.size();
        vector<int> nums(total);
        merge(nums1.begin(), nums1.end(), nums2.begin(), nums2.end(), nums.begin());
        if (total % 2 == 0) {
            return (nums[total/2] + nums[total/2 - 1]) / 2.0;
        } else {
            return nums[total/2];
        }
    }
};
```

Chapter 5

8. String to Integer (atoi)

5.1 Description

Implement the `myAtoi(string s)` function, which converts a string to a 32-bit signed integer (similar to C/C++'s `atoi` function).

The algorithm for `myAtoi(string s)` is as follows:

Read in and ignore any leading whitespace. Check if the next character (if not already at the end of the string) is '-' or '+'. Read this character in if it is either. This determines if the final result is negative or positive respectively. Assume the result is positive if neither is present. Read in next the characters until the next non-digit character or the end of the input is reached. The rest of the string is ignored. Convert these digits into an integer (i.e. "123" \rightarrow 123, "0032" \rightarrow 32). If no digits were read, then the integer is 0. Change the sign as necessary (from step 2). If the integer is out of the 32-bit signed integer range $[-2^{31}, 2^{31} - 1]$, then clamp the integer so that it remains in the range. Specifically, integers less than -2^{31} should be clamped to -2^{31} , and integers greater than $2^{31} - 1$ should be clamped to $2^{31} - 1$. Return the integer as the final result.

Note:

Only the space character ' ' is considered a whitespace character. Do not ignore any characters other than the leading whitespace or the rest of the string after the digits.

5.2 Results

Runtime: 7 ms, faster than 32.43% of C++ online submissions for String to Integer (atoi).

Memory Usage: 8.1 MB, less than 5.67% of C++ online submissions for String to Integer (atoi).

5.3 Attempt 1

Wow this problem sucked. There were so many edge cases. I guess that is why it is the second hardest problem on the site. My time complexity wasn't horrible but my space complexity was. I could probably change the stack from holding integers to pointing at the individual chars in the string. I will assuredly be coming back to this problem.

```
#define ISNUM(C) (C >= '0' && C <= '9')
#define ISLET(C) (C >= 'A' && C <= 'z')

class Solution {
public:
    int myAtoi(string s) {
        int ptr = 0;
        int n = s.length();
        bool negative = false;
        stack<int> integers;
        long int out = 0;
        if (ISLET(s[ptr])) return out;
        while (s[ptr] == ' ') ptr++;
        if (s[ptr] == '-') {
            negative = true;
            ptr++;
        } else if (s[ptr] == '+') {
            ptr++;
        }
        if (!(s[ptr] >= '0' && s[ptr] <= '9')) return 0;
        while (ptr < n) {
            if (!ISNUM(s[ptr]) || s[ptr] == '.' || s[ptr] == ' ') {
                break;
            } else {
                integers.push(s[ptr] - 48);
                ptr++;
            }
        }
        long int place = 1;
        long int tmp;
        while (!integers.empty()) {
            out += (integers.top() * place);
            if (out >= 0x80000000) return (negative) ? 0x80000000 : 0x7fffffff;
            if (place > 2147483647) {
                while (!integers.empty()) {
                    if (integers.top() > 0) return (negative) ? 0x80000000 : 0x7fffffff;
                    integers.pop();
                }
                break;
            }
            place *= 10;
            integers.pop();
        }
        return (negative) ? -out : out;
    }
};
```

Chapter 6

23. Merge K Sorted Lists

6.1 Description

You are given an array of k linked-lists lists, each linked-list is sorted in ascending order. Merge all the linked-lists into one sorted linked-list and return it.

6.2 Results

Attempt 1 Runtime: 30 ms, faster than 63.70% of C++ online submissions for Merge k Sorted Lists.

Memory Usage: 13.6 MB, less than 36.67% of C++ online submissions for Merge k Sorted Lists.

Attempt 2 Runtime: 20 ms, faster than 94.42% of C++ online submissions for Merge k Sorted Lists.

Memory Usage: 13.4 MB, less than 45.00% of C++ online submissions for Merge k Sorted Lists.

6.3 Attempt 1

Had to learn priority queues for this one, that's something they don't teach you in school. Loads each link into the queue which is then sorted as they are added then one by one links the top node of the queue to the next node in the queue.

```
/**
 * Definition for singly-linked list.
 * struct ListNode {
 *     int val;
 *     ListNode *next;
 *     ListNode() : val(0), next(nullptr) {}
 *     ListNode(int x) : val(x), next(nullptr) {}
 *     ListNode(int x, ListNode *next) : val(x), next(next) {}
 * };
 */
using namespace std;
class Compare {
public:
    bool operator() (ListNode* A, ListNode* B) {
        return (A->val > B->val);
    }
};
class Solution {
public:
    ListNode* mergeKLists(vector<ListNode*>& lists) {
        if (lists.size() == 1) return *lists.begin();
        priority_queue<ListNode*, vector<ListNode*>, Compare> pq;
        for (auto i = lists.begin(); i < lists.end(); i++) {
            auto curr = *i;
            if (!curr) continue;
            do {
                pq.push(curr);
            } while ((curr = curr->next));
        }
        auto output = (pq.empty()) ? nullptr : pq.top();
        while (!pq.empty()) {
            auto curr = pq.top();
            pq.pop();
            curr->next = (pq.empty()) ? nullptr : pq.top();
        }
        return output;
    }
};
```

6.4 Attempt 2

I had so much fun with this I decided to optimize this. Since we know the linked lists are already sorted we can just pull the leading value from each list and everytime we use a value from that list off the queue we pull another value off that corresponding list. This means we only have at most k comparisons per each insertion.

```
/**
 * Definition for singly-linked list.
 * struct ListNode {
 *     int val;
 *     ListNode *next;
 *     ListNode() : val(0), next(nullptr) {}
 *     ListNode(int x) : val(x), next(nullptr) {}
 *     ListNode(int x, ListNode *next) : val(x), next(next) {}
 * };
 */
typedef pair<ListNode*, int> p;
using namespace std;
class Compare {
public:
    bool operator() (p A, p B) {
        return (A.first->val > B.first->val);
    }
};
class Solution {
public:
    ListNode* mergeKLists(vector<ListNode*>& lists) {
        if (lists.size() == 1) return *lists.begin();
        priority_queue<p, vector<p>, Compare> pq;
        for (int i = 0; i < lists.size(); i++) {
            if (!lists[i]) continue;
            pq.push({lists[i], i});
            lists[i] = lists[i]->next;
        }
        auto output = (pq.empty()) ? nullptr : pq.top().first;
        while (!pq.empty()) {
            auto curr = pq.top();
            pq.pop();
            if (lists[curr.second]) {
                pq.push({lists[curr.second], curr.second});
                lists[curr.second] = lists[curr.second]->next;
            }
            curr.first->next = (pq.empty()) ? nullptr : pq.top().first;
        }
        return output;
    }
};
```
